

Project Readme Template

Version 1 9/11/24

A single copy of this template should be filled out and submitted with each project submission, regardless of the number of students on the team. It should have the name `readme_<teamname>`

Also change the title of this template to "Project x Readme Team xxx"

1	Team Name: RED
2	Team members names and netids: Rogelio Diaz rdiaz3
3	Overall project attempted, with sub-projects: Program 1: Tracing NTM Behavior.
4	Overall success of the project: The NTM Tracer functions correctly across all tested edge cases. Nondeterminism: It successfully branches execution flow for inputs with multiple valid paths (verified with <code>aplus.csv</code>). Tape Movement: It correctly handles bidirectional tape movement and boundary conditions (verified with <code>palindrome.csv</code>). Termination: It correctly identifies the first accepting configuration to minimize execution time, or correctly detects when all branches effectively die (rejection). Metrics: The output accurately reports the depth, total transitions, and the calculated degree of nondeterminism.
5	Approximately total time (in hours) to complete: 8 hours

9	<p>Key data structures (for each sub-project):</p> <p>Dictionary and Trees (List[List])</p>
10	<p>General operation of code (for each subproject):</p> <p>Initialization: The CSV is parsed into the dictionary, and the tree is initialized with the start state at Level 0.</p> <p>Breadth-First Loop: The code iterates through every configuration in the current level:</p> <p>Check Accept: If qacc is found, the loop breaks immediately. The "winning path" is reconstructed by following parent pointers backwards to the start.</p> <p>Check Reject: If qreject is hit or no valid transitions exist (implicit reject), that branch is abandoned.</p> <p>Expand: If the branch is alive, the code looks up valid moves (including wildcards) and appends the resulting configurations to the next level's list.</p> <p>Termination: Execution stops when an accept state is hit, the queue becomes empty (all paths rejected), or the max depth is exceeded.</p>
11	<p>What test cases you used/added, why you used them, what did they tell you about the correctness of your code.:</p> <p>N/A</p>
12	<p>How you managed the code development:</p> <p>I used the uv package manager for environment handling. Development was incremental:</p> <ol style="list-style-type: none"> 1. Verified the CSV parser correctly read the 7-line header and transitions. 2. Implemented the basic BFS loop to print configurations level-by-level. 3. Added the metrics logic (Transitions / Non-Leaves). 4. Implemented the "Parent Pointer" logic to enable the execution trace back (Section 4.2). 5. Verified output formatting against the project PDF requirements.
13	<p>Detailed discussion of results:</p> <p>The tracer successfully computed the required metrics. For deterministic inputs, the "Degree of Nondeterminism" stayed at 1.0. For the aplus machine, the degree was ~1.88, which matches the expected behavior of a machine that splits execution at nearly every step. The "winning path" output effectively filters out the noise of failed branches, showing only the correct sequence of transitions that led to acceptance.</p>

14	How the team was organized: Single-person team. I was responsible for all implementation, testing, and documentation.
15	What you might do differently if you did the project again: I would implement a verbose flag to suppress printing every configuration for deep trees (depth > 50), as the terminal output becomes difficult to read for complex problems like the composite number check. I might also consider adding a Graphviz visualization to plot the execution tree.
16	Any additional material:
